

UPDATE TO THE REPORT ON THE CONSERVATION STATUS OF
Arabis fecunda, A CANDIDATE THREATENED SPECIES

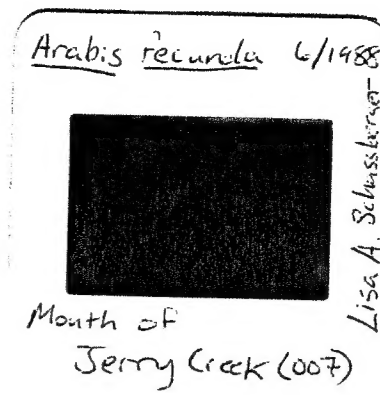

Taxon name: Arabis fecunda Rollins
Common name: Sapphire rockcress
Family: Brassicaceae (Cruciferae)
State where taxon occurs: U.S.A., Montana
Current Federal status: USFWS Notice of Review,
Category 2
Recommended Federal status: USFWS Notice of Review,
Category 2
Author of update: Lisa Ann Schassberger
Original date of report: November 15, 1985
Date of most recent revision: December 19, 1988
Individual to whom further
information and comments should
be sent:

J. Stephen Shelly
Montana Natural Heritage Program
State Library Building

Helena, MT 59620

V. New Information

21. **Record of revisions:** 19 December 1988; Lisa Ann Schassberger; Topics: I.1.D.; I.2.B.1.b.; I.2.C.1.b.; I.3.E.; I.5.A.; I.5.B.1.; I.6.A.; I.6.B.1.b.; I.6.B.4.; I.6.B.5.; I.6.C.1.; I.6.C.6.; I.7.A.; I.7.B.1.; I.7.B.2.; I.7.C.1.: a., b., c., d., e., f., g., h., i., j., k., l.; I.7.D.4.; I.7.D.6.; I.8.C.2.b.; I.9.A.; I.9.B.; I.9.C.; I.9.D.; I.11.A.1.; II.12.; II.13.A.; II.13.B.1.; II.15.A.1.; II.15.A.2.; II.16; III.17.C.1.; III.17.D.; III.18.; Note: Within the text, numbers in parentheses following site names refer to the three-digit occurrence numbers, see Table 1 (p. 4).

- I.1.D. **History and knowledge of taxon:** Since 1985, the sites in the foothills of the Sapphire Range in Ravalli County, Montana were resurveyed. Additional subpopulations were added to the three previously known sites and one new population was discovered. Additionally, eight new populations were located along the north and east flanks of the Pioneer Mountains, in Beaverhead and Silver Bow counties.
- I.2.B.1.b. **Other current formal status recommendations:** The status of Arabis fecunda will be changed to "endangered throughout range" (global rank = G2) by the Montana Natural Heritage Program.
- I.2.C.1.b. **Other current formal status recommendations:** The status of Arabis fecunda will be changed to "endangered" in Montana (state rank = S2) by the Montana Natural Heritage Program.
- I.3.E. **Photographs and line drawings:** The color slides (p.2) are duplicates of those taken at the sites indicated. Additional slides of Arabis fecunda and its habitat are housed at the office of the Montana Natural Heritage Program, Helena, Montana.
- I.5.A. **Geographical range:** With the addition of nine new sites, Arabis fecunda is now known to occur at elevations from 4,600-8,000 ft. A new site (1986) from the foothills of the Sapphire Range occurs along Birch Creek in Ravalli County, Montana. The sites discovered in 1988 occur along the Big Hole

River, and in several smaller drainages on the north and east flanks of the Pioneer Mountains, including: Jerry Creek, Quartz Hill Gulch, Canyon Creek and Birch Creek. These sites fall within Beaverhead and Silver Bow counties, Montana. The new sites along the flanks of the Pioneer Mountains extend the range of this species ca. 75 miles to the southeast. The global distribution for this species is shown on Map 1, p. 4.

I.5.B.1.

Populations currently known extant:

- e. **Montana:** Populations are listed in Table 1, pp. 5-6; exact locations are provided on Maps 2-8, pp. 7-13. All twelve extant populations are included in these tables and maps, as additional subpopulation were discovered for the three sites described in the original report.

I.6.A.

Concise statement of general environment and habitat: Populations are now known to occur up to 8,000 ft. in elevation.

I.6.B.1.b.

Regional macroclimate: The long-term weather station nearest to the newly discovered populations in the Pioneer Mountains is at Divide, approximately 11 miles east of the sites, at 5,395 ft. in elevation. For the period from 1951-1980, the July mean temperature was 63.3 °F, the January mean was 19.1 °F, and the average annual precipitation was 12.39 in. (Department of Commerce, 1982).

I.6.B.4.

Physiographic and topographic characteristics: The new sites along the flanks of the Pioneer Mountains occur on the Madison Limestone Formation, comprised of metamorphosed limestone and sandstones, and on the Threeforks Formation, comprised of grayish-brown argillaceous limestone (Richards and Pardee, 1925). These sites appear to be on substrates similar to those occupied by the Sapphire Range populations.

I.6.B.5.

Edaphic factors: Arabis fecunda may be associated with cryptogamic soil crusts. The initial results of ongoing monitoring and ecological studies in Ravalli County are included in Appendix B, p. 36 (Lesica and

Map 1. Distribution of Arabis fecunda populations; the species is endemic to western Montana.

Lime Gulch (012)

Shelly, 1988). This report details the possible influence of soil crust on this species.

I.6.C.1.

Vegetation, physiognomy and community structure: Sites in the Pioneer Mountain drainages are often under a very sparse overstory of Juniperus scopulorum (Rocky Mountain juniper), Pseudotsuga menziesii (Douglas fir) and Pinus ponderosa (ponderosa pine). The dominant shrubs are Cercocarpus ledifolius (curly-leaf mountain mahogany) or Artemisia tridentata (big sagebrush). The associated species at the new site in the foothills of the Sapphire Range, Birch Creek Bluffs (004), are similar to those previously reported from that area.

I.6.C.6.

Dependence on dynamic aspects of biotic associations and ecosystem features: Arabis fecunda may be influenced by the presence and abundance of Centaurea maculosa (spotted knapweed) at the sites along the eastern edge of the Sapphire Mountains. A report on detailed studies of these effects is included in Appendix B, p. 36 (Lesica and Shelly, 1988).

I.7.A.

GENERAL SUMMARY: Additional subpopulations and/or numbers of plants were recorded for the three sites in the original report. Charleys Gulch (001) now includes thirteen subpopulations and contains approximately 8,000-10,000 plants. Spring Gulch (002) now includes four subpopulations containing approximately 1,000-1,500 plants. Rock Quarry Gulch (003) still consists of only one population, but additional plants were recorded for this site, bringing the total number to approximately 800-1,000. The new Birch Creek Bluffs (004) population has six subpopulations, with approximately 10,000+ plants, within a radius of 3/4 mile.

Populations and subpopulations in the Pioneer Mountain drainages consist of from 75-10,000 plants. These populations are within a radius of ca. 16 miles of one another. The largest distance separating all known populations is ca. 95 miles (between the Lime Gulch (012) site in the Pioneer Mountains, and the Sapphire Mountain populations).

I.7.B.1.

KNOWN POPULATIONS: Nine new populations of Arabis fecunda have been discovered since 1985; the total number is now twelve. Eight of these populations occur along the north and east flanks of the Pioneer Mountains and one additional population was found in the foothills of the Sapphire Range. The Element Occurrence records for each of these populations is found in Appendix A, p. 23.

I.7.B.2. a.**Charleys Gulch**

1. **Area:** Thirteen subpopulations covering a total area of ca. 700 acres.
2. **Number and size of plants:** ca. 8,000-10,000+ plants.
3. **Density:** Plant density is often high in localized areas within the site.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of flowering and fruiting plants.
6. **Evidence of expansion/contraction:** None.

b. Spring Gulch

1. **Area:** Four subpopulations covering a total area of ca. 160 acres.
2. **Number and size of plants:** ca. 1,000-1,500 individual plants.
3. **Density:** Plants sparsely distributed within the site.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of flowering and fruiting plants.
6. **Evidence of expansion/contraction:** None.

c. Rock Quarry Gulch

1. **Area:** One population covering a total area of ca. 5 acres.
2. **Number and size of plants:** ca. 800-1,000+ individual plants.
3. **Density:** Plant density intermediate within the site.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of flowering and fruiting plants.
6. **Evidence of expansion/contraction:** None.

d. Birch Creek Bluffs

1. **Area:** Six subpopulations covering a total area of ca. 200 acres.

2. **Number and size of plants:** ca. 10,000+ individual plants, ca. 60% in flower and 20% in fruit in 1986.
3. **Density:** Arabis fecunda frequent in some areas within the site.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of flowering and fruiting plants.
6. **Evidence of expansion/contraction:** None.

e. **Quartz Hill**

1. **Area:** One population with scattered individuals. Total area occupied by Arabis fecunda is ca. 5 acres.
2. **Number and size of plants:** No estimate of population size available.
3. **Density:** Scattered individual plants.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of plants with mature fruits.
6. **Evidence of expansion/contraction:** None.

f. **Mouth of Quartz Hill Gulch**

1. **Area:** Eight subpopulations, over ca. 100 acres.
2. **Number and size of plants:** ca. 7,300 plants, ca. 25% in flower and 15% in fruit in 1988.
3. **Density:** Density of Arabis fecunda high in some areas within the largest subpopulations; otherwise, individual plants were scattered.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of mature fruits.
6. **evidence of expansion/contraction:** None.

g. **Jerry Creek**

1. **Area:** Two subpopulations over ca. 40 acres.
2. **Number and size of plants:** ca. 5,000 plants, ca. 50% with mature fruit in 1988.
3. **Density:** Plant density fairly high in the largest subpopulation, with ca. 20% total cover of Arabis fecunda in some areas; remaining plants scattered.
4. **Presence of dispersed seed:** Unknown.

5. **Evidence of reproduction:** Presence of mature fruits.
6. **Evidence of expansion/contraction:** None.

h. Upper Quartz Hill Gulch

1. **Area:** One population on ca. 40 acres.
2. **Number and size of plants:** ca. 75-100 plants, ca. 15% in fruit and 25% in flower in 1988.
3. **Density:** Scattered.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of mature fruit.
6. **Evidence of expansion/contraction:** None.

i. Spring Gulch II

1. **Area:** One population scattered over ca. 2 acres.
2. **Number and size of plants:** ca. 100-200 plants, most in fruit in 1988.
3. **Density:** Scattered.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of mature fruit.
6. **Evidence of expansion/contraction:** None.

j. Big Hole River

1. **Area:** One population scattered over 1 acre.
2. **Number and size of plants:** ca. 100 plants, 90% in fruit in 1988.
3. **Density:** Scattered.
4. **Presence of dispersed seed:** Unknown.
5. **Evidence of reproduction:** Presence of mature fruit.
6. **Evidence of expansion/contraction:** None.

k. Vipond Park

1. **Area:** Two subpopulations, covering 100 acres.
2. **Number and size of plants:** ca. 10,000 plants, ca. 15% in flower and 60% in fruit in 1988.
3. **Density:** Very dense cover of Arabis fecunda occurs in portions of the site.
4. **Presence of dispersed seed:** Unknown.

- 5. **Evidence of reproduction:** Presence of mature fruit.
- 6. **Evidence of expansion/contraction:** None.

1. **Lime Gulch**

- 1. **Area:** One large population covering 80 acres.
- 2. **Number and size of plants:** ca. 10,000 plants, ca. 90% in fruit in 1988.
- 3. **Density:** Greater than 20% cover of Arabis fecunda within parts of the site.
- 4. **Presence of dispersed seed:** Unknown.
- 5. **Evidence of reproduction:** Presence of mature fruit.
- 6. **Evidence of expansion/contraction:** None.

I.7.C.

- 1. **Patterns:** The Pioneer Mountain sites were first visited in early July of 1988. At that time, five of the eight populations were still partially in flower. These high elevation sites extend the flowering dates for the known populations into early July, and fruiting is likely to occur through mid- or late July.

I.7.D.4.

Seed biology

- a. **Amount and variation of seed production:** There appears to be some variation with respect to yearly seed production by Arabis fecunda at some sites. See Appendix B, p. 36 (Lesica and Shelly, 1988) for detailed information.

I.7.D.6.

Survival and mortality: Mortality and recruitment appear to be nearly equal in some populations of Arabis fecunda; however, disturbance by livestock may have an influence on these processes at some sites. See Appendix B, p. 36 (Lesica and Shelly, 1988) for detailed information.

I.8.C.2.

- b. **Interspecific:** The exotic weed Centaurea maculosa (spotted knapweed) may have an influence on populations of Arabis fecunda. A report from an ongoing study of the interactions between these two species, from sites

near the Sapphire Range, is contained in Appendix B, p. 36.

I.9.A. General nature of ownership: The sites in the Pioneer Mountain drainages are on U.S.D.A. Forest Service, U.S.D.I. Bureau of Land Management, and State of Montana lands.

I.9.B. Specific landowners:

1. USDA Forest Service
Beaverhead National Forest
610 N. Montana Street
Dillon, MT 59725
2. USDI Bureau of Land Management
Headwaters Resource Area
P.O. Box 3388
Butte, MT 59702
3. Montana Department of State Lands
1625 11th Avenue
Helena, MT 59620
4. Several sites are partially or wholly privately owned. These include:
 - Charleys Gulch (001)
 - Spring Gulch (002)
 - Rock Quarry Gulch (003)
 - Birch Creek Bluffs (004)
 - Wise River (010)

I.9.C. Management responsibility: Same as ownership.

I.9.D. Easements, conservation restrictions, etc.: A portion of the Charleys Gulch Site is registered with The Nature Conservancy by the owner (George Frost). Although such registry is not legally binding, the owner agrees to preserve the populations present, and to inform The Nature Conservancy of any proposed land management changes.

I.11.A.1. Present or threatened destruction, modification, or curtailment of habitat or range: The Birch Creek Bluffs population (004) may be threatened by weed invasion by Centaurea maculosa (spotted knapweed). The Mouth of Quartz Hill Gulch subpopulation (006) closest to the road is threatened by gravel removal from the base of the hill.

The Jerry Creek population (007) is threatened by grazing and trampling by cattle. The lower portion of the hill where this population occurs was heavily trailed and disturbed.

II.12.

General assessment of vigor, trends and status: Arabis fecunda is now known from twelve populations, within a radius of ca. 47 miles. Centaurea maculosa (spotted knapweed) is currently not a threat to populations along the flanks of the Pioneer Range, but may pose a threat to the Birch Creek Bluffs site in the foothills of the Sapphire Range. Reproductive output and vigor of Arabis fecunda appears to be normal at the newly discovered sites.

II.13.A.

Recommendation to U.S. Fish and Wildlife Service: Peter Lesica submitted a petition to list Arabis fecunda just prior to the discovery of the new populations along the flanks of the Pioneer Mountains. Subsequent to these discoveries the petition was retracted. It is recommended that Arabis fecunda be retained in Category 2 until further distribution and ecological studies can be conducted.

II.13.B.

U.S. Forest Service: Arabis fecunda is now known to occur on lands administered by the U.S. Forest Service. Thus, it should be placed on the list of sensitive species in Region 1 for Montana.

II.15.A. 1.

Recommendations regarding present or anticipated activities: The effects of mining or increased grazing in areas supporting populations of Arabis fecunda should be assessed before any of these activities are implemented.

2.

Areas recommended for protection: The Vipond Park site (011) is a large, representative population of Arabis fecunda on Forest Service lands, and should be proposed for special designation. The Quartz Hill site (005), although not yet thoroughly surveyed, is recommended for protection because of its close proximity to two other rare plant populations (Penstemon lemhiensis (Lemhi penstemon) and Claytonia lanceolata var. flava (yellow springbeauty)). Both of these

are USFWS Category 2 taxa and USFS Region 1 sensitive species.

December 1988

INTRODUCTION

In order to adequately protect populations of an organism, it is necessary to understand its life history and population dynamics (Massey and Whitson 1980; Sutter 1986; Palmer 1987). In addition, many rare species are threatened by interactions with non-native species that have been introduced into their habitat (Drake 1988). It is important to understand the nature of these interactions in order to protect populations of rare species from extinction.

Arabis fecunda Rollins (Sapphire rockcress) is a rosette-forming perennial in the mustard family (Brassicaceae). This recently described species (Rollins 1984) is endemic to highly calcareous, azonal soils in the foothills of the Sapphire and Pioneer mountains in Ravalli, Beaverhead and Silver Bow counties, Montana (Lesica 1985; Schassberger 1988). Arabis fecunda occurs on eroding slopes with low vascular plant density but a relatively high cover of cryptogamic soil crust. Populations of A. fecunda are thought to be threatened by livestock grazing and encroachment by Centaurea maculosa Lam. (spotted knapweed), an aggressive exotic weed (Lesica 1985; Schassberger 1988).

This paper is a progress report on three studies being conducted on populations of A. fecunda in Ravalli County. The studies and their purposes are:

1. Long-term monitoring of A. fecunda populations in order to determine important life history attributes and trends in overall recruitment and mortality.
2. Spotted knapweed removal study, in order to determine the effects of knapweed competition on the performance of A. fecunda.
3. Soil crust ecology study, in order to assess the importance of soil crust to the establishment and survival of A. fecunda plants.

METHODS

Study Areas

Studies were conducted at two Arabis fecunda sites in Ravalli County, Montana: Charleys Gulch and Birch Creek. The Charleys Gulch site is on a steep, eroding, southwest-facing slope along the drainage at an elevation of ca. 1524 m. (5000 ft.) (T6N R19W S29, NW1/4). The Birch Creek site is on a steep, eroding, southeast-facing slope above the creek at an elevation of ca. 1433 m. (4700 ft.) (T7N R19W S16, NW1/4). Complete descriptions of the study sites can be found in Lesica (1985) and Schassberger (1988).

Long-term Monitoring Study

In May, 1987, we established permanent belt transects of 12 adjacent 1 m² plots at both sites following the methods outlined in Lesica (1987). Individual A. fecunda plants were mapped and recorded using the following system:

- S = seedling
- R = the number of rosettes per plant
- I = the total number of inflorescences (stems) per plant
- F = the total number of fruits produced by the plant

Thus, a plant with two rosettes, three stems and a total of nine fruits would be recorded as R1-I3-F9. Seedlings were recognized by their small size and the absence of leaves from the previous year. In addition, we noted the presence of recently disturbed soil and evidence of livestock trampling. We did not record seedlings at the Birch Creek site in 1987. The transects were read on May 19-20, 1987 and 1988.

Knapweed Removal Study

In May, 1987, we established permanent belt transects consisting of 10 adjacent 1 m² plots at each of the study sites following the methods of Lesica (1987). Transects were placed in areas with relatively heavy knapweed infestations. Individual A. fecunda plants were mapped and recorded as in the long-term monitoring study. For each transect, we removed the knapweed from five randomly selected plots by carefully cutting the plants below the root crown with a sharp knife. Knapweed was removed from plots 2,4,5,8, and 9 at Birch Creek and from plots 1,4,5,8, and 9 at Charleys Gulch. We did not record seedlings at the Birch Creek site in 1987. The transects were read on May 19-20, 1987 and 1988.

Soil Crust Ecology Study

In order to determine whether there is an association between intact cryptogamic soil crust and the distribution of A. fecunda, we estimated cover of soil crust and bare ground in belt transects consisting of adjacent 1 m² plots. These transects were chosen to be representative of the steep, highly erodible slopes where A. fecunda is most frequent. We measured cover of bare ground and soil crust using a point-frequency frame (Mueller-Dombois and Ellenberg 1974, p. 86). The frame was 1 X 1 m with 20 equally-spaced pins. In each plot, the pins were dropped to the surface and the number of hits on bare soil and soil crust was recorded. Hits on exposed rock were not included in subsequent analyses. The diameter of the pins was approximately equal to the diameter of a taproot of A. fecunda (ca. 0.1 in). In addition, we recorded the number of A. fecunda plants rooted in the soil crust and the total number of A.

fecunda plants in each 1 m² plot. At Charleys Gulch, we read two transects (10 and 12 plots), and at Birch Creek, we read one transect (22 plots). All of the transects were located in areas subject to livestock grazing. Transects were read on May 19-20, 1988.

RESULTS AND DISCUSSION

Long Term Monitoring Study

A summary of the data from two years of the long-term monitoring study is presented in Table 1. At both sites the density of plants was slightly lower in 1988 than in 1987. In addition, the number and percentage of fruiting plants was appreciably lower in 1988 than in 1987. At both sites, however, the total number of fruits per fertile plant, and the number of fruits per inflorescence, was greater in 1988. These results probably indicate various stress responses to the drought conditions that began in 1987 and continued into 1988.

Size and fecundity data for individual Arabis fecunda plants over the two-year period are presented in Appendix A. These data are summarized in Table 2. It is too early in the study to determine whether these populations are stable, growing or declining; nonetheless, it is worth noting some trends. At Charleys Gulch, where only one plant was lost to apparent soil slumping, recruitment and adult mortality were approximately equal in both years. At Birch Creek, where 15 plants were lost to soil slumping, adult mortality was appreciably higher than recruitment. In most cases of soil slumping at Birch Creek, we observed hoof prints of cattle in the slumped areas. If these 15 plants had not been lost, mortality and recruitment would have been approximately equal. At Charleys Gulch, apparent seedling survival was greater than seedling mortality. However, these results have limited meaning because appreciable seedling mortality may have occurred prior to reading the transects in late May.

Knapweed Removal Study

One year after removing spotted knapweed plants from the experimental plots, its cover was approximately equal to that in the control plots (Table 3). This result can be explained in part by new recruitment of seedlings and in part by a failure to completely eradicate all plants in 1987. Nonetheless, the competitive ability of knapweed in the removal plots should have been reduced during at least part of the 1987 growing season.

	1	2	3	4	5	6	7	8	9	10		
1987	20	25	20	25	28	23	20	23	30	25	23	25
1988	5	20	28	15	18	30	25	23	18	35	28	16

Birch Creek #2												
Year		*		*	*			*	*		Control Mean	Removal Mean
	1	2	3	4	5	6	7	8	9	10		
1987	30	35	35	30	33	38	28	23	23	28	32	29
1988	30	20	30	30	20	30	15	30	30	20	25	26

Density and fecundity data for plants of A. fecunda in removal and control plots are presented in Table 4. In general, these data show the same trends as found in the long-term monitoring study: a drastic reduction in number and percent of plants fruiting and an increase in the average number of fruits per inflorescence and per fruiting plant in 1988 (see above for discussion). Density of A. fecunda plants at Charleys Gulch showed no increase in 1988 in either the control plots or the removal plots. At Birch Creek, while control plots showed no appreciable increase in density of A. fecunda plants in 1988, there was a more than three-fold increase in the removal plots. The density of A. fecunda in individual removal and control plots in 1987 and 1988 at Birch Creek are presented in Table 5. Between 1987 and 1988, density decreased slightly in all but one of the control plots, while density increased in all but one of the knapweed removal plots. Our notes from 1987 indicate that there were large numbers of seedlings in plots 8, 9, and 10. Many of these survived in the removal plots (plots 8 and 9), but few survived in the control plot (plot 10). These results suggests that A. fecunda recruitment may be curtailed by the presence of knapweed.

Soil Crust Ecology Study

In this study, the null hypothesis is that within the three belt transects Arabis fecunda plants are distributed at random, i.e., without respect to the presence of soil crusts. The results of a chi-square analysis of the data are presented in Table 6. The null hypothesis was strongly rejected in all three cases, indicating that the distribution of A. fecunda is not random. The data show that A. fecunda is associated more often with soil crusts than bare soil within the transects. There are two possible explanations for these results: (1) A. fecunda is able to establish and survive better in soil crusts, and/or (2) A. fecunda is able to establish and survive with equal success in bare soil and soil crusts; however, perturbations caused by livestock destroy not only the A. fecunda plants growing in bare soil and soil crust, but also the soil crust itself. This would result in an increase in the amount of bare soil without A. fecunda. These two explanations are not mutually exclusive.

If the first explanation is correct, A. fecunda may be dependent on the presence of soil crusts to maintain viable population levels within these transects. Grazing by livestock has been shown to reduce the cover of soil crusts (St. Clair et al. 1984), thus reducing the availability of microsites which are important for seedling establishment and survival. If the second explanation is correct, livestock grazing is destroying A. fecunda plants in these transects regardless of whether they are rooted in bare soil or soil crusts. Under either interpretation, our results indicate that livestock grazing is detrimental to populations of A. fecunda on the steep, highly erodible slopes in these transects.

CONCLUSIONS

All of the studies reported on are still in progress, and any conclusions must be considered tentative until more data has been collected. Nonetheless, several trends are apparent and are worthy of comment. Results of the long-term monitoring and soil crust ecology studies suggest that livestock grazing on the steep highly erodible slopes, where the transects were located, is destructive, and is probably detrimental to the long-term viability of Arabis fecunda populations. Results of the knapweed removal study suggest that, under certain circumstances, spotted knapweed may be inhibiting recruitment of Arabis fecunda seedlings. Thus, both livestock grazing and knapweed encroachment may pose a threat to populations of Arabis fecunda.
